ABSTRACT The goal of this program on Photorefractive polymers are to improve the performance of photorefractive polymers and to fabricate innovative devices based on these highly efficient materials. During the lifespan of the program we have made significant progress in the following areas: (1) madeling of photorefractive polymers. During the lifespan of the program we have made significant programs in the following areas: (1) modeling of photorefractive polymers. During the course of the investigation we published (with AFOSR acknowledgements) 12 papers in refereed journals and 5 book chapters and gave 32 invite		TITLE			+

Final report

Under current AFOSR grant # F49620-99-1-0021 for which I was a co-Investigator with Prof. Nasser Peyghambarian who was the principal investigator, we have obtained numerous significant results in the development of photorefractive polymers for holographic storage and optical processing applications. During the course of this investigation we published (with AFOSR acknowledgments) 12 papers in refereed journals and 5 book chapters and gave 32 invited talks at international conferences and workshops.

The goals of our AFOSR program on photorefractive polymers were to improve the performance of photorefractive polymers and to fabricate innovative devices based on these highly efficient materials. A central objective of our program was to achieve destructive read-out in an organic photorefractive material. This was achieved recently and the work will appear in December 2001 in Optics Letters. It can be considered a major milestone in the development of photorefractive polymers.

During the lifespan of the program we have made significant progress in the following areas: (i) material fabrication and characterization; (ii) modeling of photorefractivity in polymers; (iii) development of new applications based on photorefractive polymers. Specifically:

• We demonstrated the recording of holograms and their non-destructive read-out in a photorefractive polymer using two-photon absorption. Sensitivity was provided by the excitation of the electro-active chromophore with femtosecond pulses followed by charge injection into the photoconducting PVK matrix. The holograms could be fully erased with a pulsed laser source but were insensitive to cw laser beams with the same wavelength. Studies of the field and intensity dependence of the diffraction efficiency indicate that the holograms are formed through the photorefractive effect. In our experiments we used 105 µm-thick samples of the photorefractive polymer composite FTCN:PVK:BBP:ECZ (25:55:10:10 wt. %) sandwiched between two ITO coated transparent electrodes. The composite contained the electro-active chromophore FTCN, the photoconducting polymer matrix poly(N-vinylcarbazole) (PVK), and the plasticizers N-ethylcarbazole (ECZ) and benzyl butyl phthalate (BBP). Sensitization in this case was achieved through TPA in the electro-active dopant molecule FTCN. As shown in Fig. 1, these new samples are yellow and have no linear absorption at the operating wavelength of 650 nm. Holographic recording was achieved through four-wave mixing experiments with 130 fs pulses at a wavelength of 650 nm produced at a repetition rate of 1 kHz by an optical parametric amplifier pumped by the amplified output of a Ti:Sapphire laser system. To demonstrate non-destructive read-out we changed the wavelength of the pulsed laser source experiments to 700 nm and replaced the pulsed reading beam with a cw laser diode emitting at the same wavelength. No changes in diffraction efficiency could be detected for several minutes with a reading power as high as 5 mW, that is an order of magnitude higher than the average power of the pulsed writing beams. However, when one of the pulsed writing beams was blocked, the grating could be erased completely within a few seconds by the remaining spatially uniform writing beam.

Fig. 1: Photograph of a photorefractive polymer sensitized by two-photon absorption.

• We demonstrated the fabrication of photorefractive polymer composites using injection molding (see Fig. 2). This work is a proof-of-principle demonstration that photorefractive polymers can be fabricated using mass production techniques. For our experiments we formulated a photorefractive composite that was known to have good phase stability properties and a high dynamic range. The inert polymer was a commercial birefringence-free acrylic resin, doped with the photorefractive chromophore 2, N, N-dihexylamino-7-dicyano-methyl-idenyl-3, 4, 5, 6, 10-pentahydro-naphthalene (DHADC-MPN), that provides simultaneously transport properties and electro-activity. The composite was plasticized using diphenyl isophthalate (DIP), and sensitized using (2,4,7-trinitro-9-fluorenylidene)-malononitrile (TNFDM).

Fig. 2: Photograph of a photorefractive polymer sample fabricated by injection molding

- By getting more insight into the formation of photorefractive traps and by controlling its concentration by adjusting the relative energies of the HOMO levels of the different constituents in photorefractive polymer composites we have been able to fabricate new materials that combine high dynamic range and fast response time. By using two different plasticizers, we obtained new composites in which overmodulation of the diffraction efficiency is observed at 60 V/µm with response times that are video compatible.
- A photorefractive polymer composite with a 2-millisecond response time was developed. To the best of our knowledge, this is the fastest response time yet reported in a polymer. Transient ellipsometric measurements directly confirm that in this system

chromophore orientational time does not limit the photorefractive response-time (Fig. 3). These new, fast materials are based on a fluorinated chromophore which combines good stability and high orientational mobility with useful dynamic range.

Fig. 3: Build-up dynamics of a hologram recorded in the photorefractive polymer composite FTCN:PVK:ECZ:TNFDM with a 2 ms time constant. The solid curve is the calculated build-up dynamics assuming that the orientational dynamics of the chromophore is the limiting factor.

The National Environmental Policy Act of 1969 (NEPA) requires Federal agencies to consider potential environmental concerns of major federal undertakings. This includes research projects funded by the Air Force Office of Scientific Research (AFOSR). Under the Air Force Environmental Impact Analysis Process, all projects must have an environmental assessment or environmental impact statement completed UNLESS they qualify for a categorical exclusion from this requirement. In order to qualify for this categorical exclusion, proposed research must be normal and routine basic or applied research confined to the laboratory and in compliance with all safety, environmental, and natural resource conservation laws. The following documentation must be completed in order to assist AFOSR in determining whether the proposed research meets the criteria for such categorical exclusion.
